Inotropic action of 6-thioguanine-induced lymphocytes in vitro. The influence of a low (1 micrograms/ml) and a high (10 micrograms/ml) concentration of 6-thioguanine, an anti-metabolite used in the treatment of immunodeficiency, on the contractile activity of isolated guinea-pig atria was studied. A strong inhibitory effect was observed on the inotropic action of stimulation induced by adrenaline or by electrical stimulation of the sympathetic nerve. A similar but less pronounced effect was observed on the negative inotropic action of blockade of Ca^{++} channels. The results are discussed in relation to the in vivo status of the organism under the influence of 6-thioguanine and the importance of the inotropic and chronotropic effects of this drug.

Long-distance electron transfer in a protein-bound phloroglucinol-cobalt(II) complex. The phloroglucinol-cobalt(II) complex is a model system for studying electron-transfer reactions involving protein-bound cofactors. The principal goal of this research is to develop a simple, effective method for moving electron pairs over long distances within proteins in vitro. A model system for this study is a mutant horseradish peroxidase (HRP) in which the essential cysteine heme thiol group has been oxidized to form a mixed-valence state through reaction with the cyano-radical intermediate formed from the cobalt(II)-phloroglucinol system.

We have demonstrated that the phloroglucinol-cobalt(II) complex catalyzes the oxidation of HRP's cysteine thiolate heme groups to form the product, 4-amino-benzoate 1,6-dioxygenase, with a half-maximal rate in the three-second range at pH 7.0. With this information, we have developed a simple model system, which consists of phloroglucinol (Pg), cobalt(II), horseradish peroxidase (HRP) and an electrochemical electrode (at 0 V vs. saturated calomel electrode). Under oxidizing conditions, the rate of the phloroglucinol-cobalt(II)
