The present invention relates to improving the process of fabricating a semiconductor device. More particularly, the present invention relates to reducing the total number of steps for fabricating a semiconductor device. In a typical semiconductor fabrication process, a number of electronic devices are fabricated on a single wafer. The individual devices are then separated or packaged as individual units. Usually, the packaging involves mounting the electronic devices to a substrate for purposes of protecting the devices against damage and of simplifying the process of testing and handling the devices. One common type of packaging is referred to as a flip-chip package. In a flip-chip package, a number of contacts on the face of the die are used to connect the die to the package. Typically, the package is connected to other circuitry using bond wires. Package configurations have been developed to permit greater numbers of die to be integrated in a single package. One
